1 Changes in Response to Feedback

The below sections are the feedback and response to the feedback throughout the course, grouped by the related documents. Note that feedback in relation to simple styling, spelling or syntax of the documents were excluded.

[Summarize the changes made over the course of the project in response to feedback from TAs, the instructor, teammates, other teams, the project supervisor (if present), and from user testers. —TPLT]

[Version control can make the summary relatively easy, if you used issues and meaningful commits. If you feedback is in an issue, and you responded in the issue tracker, you can point to the issue as part of explaining your changes. If addressing the issue required changes to code or documentation, you can point to the specific commit that made the changes. Although the links are helpful for the details, you should include a label for each item of feedback so that the reader has an idea of what each item is about without the need to click on everything to find out. —TPLT]

[If you were not organized with your commits, traceability between feedback and commits will not be feasible to capture after the fact. You will instead need to spend time writing down a summary of the changes made in response to each item of feedback. —TPLT]

[You should address EVERY item of feedback. A table or itemized list is recommended. You should record every item of feedback, along with the source of that feedback and the change you made in response to that feedback. The response can be a change to your documentation, code, or development process. The response can also be the reason why no changes were made in response to the feedback. To make this information manageable, you will record the feedback and response separately for each deliverable in the sections that follow. —TPLT]

[If the feedback is general or incomplete, the TA (or instructor) will not be able to grade your response to feedback. In that case your grade on this document, and likely the Revision 1 versions of the other documents will be low. —TPLT]

1.1 SRS and Hazard Analysis

1.2 Design and Design Documentation

1.2.1 Module Interface Specification (MIS)

The MIS revisions focused on improving consistency, abstraction, traceability, and clarity of interfaces. Feedback items were grouped by source and mapped to the final document so that each change can be traced back to the review that motivated it.

Table 1: MIS feedback and response traceability

Source	Feedback	Change Made	Where Addressed
TA Review #200, annotated MIS.pdf	Use `bool` instead of Boolean for consistency.	Revised the type notation to use `bool` consistently in the MIS. This aligned the type names with the notation table and removed inconsistent wording.	Issue #265; Section 4.3, Table 2
TA Review #200, annotated MIS.pdf	Define variables using the names intended for the implementation.	Revised variable names to better match the intended system terminology and to improve consistency between the MIS and implementation-facing documentation.	Issue #264; Sections 4.4 and 6
TA Review #200, annotated MIS.pdf	Clarify local functions, or reconfigure modules so that the module interfaces remain meaningful.	Added local functions where appropriate and revised module descriptions to better justify the structure of the affected modules.	Issue #263; Section 6
TA Review #200, annotated MIS.pdf	Clarify whether the Browser Module functions as the system's main runtime entry.	Revised the Browser Module description to state that it provides the runtime container for the client application and clarified its role in the system.	Issue #262; Section 6.1

Source	Feedback	Change Made	Where Addressed
TA Review #200, annotated MIS.pdf	Refer to the module decomposition table explicitly by number.	Revised the introductory text for module decomposition so that it explicitly refers to Table 3.	Issue #261; Section 5, Table 3
Peer Review #239	The MIS is missing abbreviations and acronyms needed for readability.	Expanded the symbols, abbreviations, and acronyms section to improve clarity and make the document easier to read independently.	Section 2, Table 1
Peer Reviews #217 and #218	Module subsections, module types, and input/output types are unclear.	Standardized the MIS structure across modules and clarified exported access programs by making inputs, outputs, and exceptions more explicit.	Section 4.3, Table 2; Section 6
Peer Reviews #212 and #223	The level of abstraction and module hierarchy need to be more precise.	Revised the module decomposition and updated module descriptions and uses clauses so that the hierarchy and abstraction boundaries are more consistent.	Section 5, Table 3; Section 6
Final Documentation Issue #501 (sub-issues #481 to #485)	Remove unnecessary text, clarify parameters and outputs, fix formatting, and hyperlink module references.	Removed unnecessary content, clarified parameter meanings and data types, defined outputs for exported access programs, corrected formatting issues, and added hyperlinks to module references.	Section 6

1.3 VnV Plan and Report

1.3.1 VnV Plan

This subsection summarizes the feedback received on the Verification and Validation (V&V) Plan and the revisions made in response. The updates focused on improving traceability, clarifying verification approaches, strengthening test descriptions, and refining the structure and readability of the document.

Table 2: V&V Plan feedback and response traceability

Source	Feedback	Change Made	Where Addressed
TA Review #130, annotated VnVPlan.pdf	Traceability table contains unnecessary columns.	Simplified the traceability table by removing redundant columns and retaining only essential mappings between test IDs and requirement identifiers.	Section 4.3, Table 9
TA Review #130, annotated VnVPlan.pdf	Traceability between test cases and requirements is unclear.	Revised the traceability table to explicitly map each test ID to corresponding SRS and non-functional requirement identifiers, improving clarity and coverage justification.	Section 4.3
TA Review #130, annotated VnVPlan.pdf	Verification approach is ambiguous and difficult to follow.	Rewrote verification approach descriptions to clearly connect testing methods (unit, UI, manual, automated) with the corresponding test cases and system components.	Section 4.1; Section 4.2
TA Review #130, annotated VnVPlan.pdf	Test case descriptions are incomplete and include unnecessary columns.	Refined test case tables by removing unnecessary columns and ensuring each test clearly specifies procedure, expected outcome, and linked requirements.	Section 4.1.1–4.1.3
TA Review #130, annotated VnVPlan.pdf	Unclear whether tests are manual or automated.	Explicitly distinguished between automated and manual tests in the verification approach sections and tool descriptions.	Section 3.5; Section 3.6; Section 4
TA Review #130, annotated VnVPlan.pdf	Descriptions of testing tools are vague.	Improved Table 5 by clarifying the purpose of each tool (testing, automation, CI/CD, static analysis, and API validation).	Section 3.6, Table 5
TA Review #130, annotated VnVPlan.pdf	Unclear ownership of verification activities.	Clarified team responsibilities and roles in verification activities, including testing, reviews, and traceability management.	Section 3.1, Table 4

Source	Feedback	Change Made	Where Addressed
TA Review #130, annotated VnVPlan.pdf	Usability evaluation is not fully specified.	Expanded usability testing to include task-based evaluation, performance metrics (time, clicks), and survey-based feedback with quantitative thresholds.	Section 4.2.3; Appendix 7.2
TA Review #130, annotated VnVPlan.pdf	Ambiguity between SRS walkthroughs and code walkthroughs.	Clarified distinction between SRS verification walkthroughs and code walkthroughs, and placed them in appropriate sections of the plan.	Section 3.2; Section 3.5
TA Review #130, annotated VnVPlan.pdf	Missing list of tables and figures based on rubric.	Added structured contents including tables and appendix references to align with documentation expectations.	Contents page
Peer Review #461	Traceability between VnV Plan and VnV Report is insufficient.	Ensured consistent identifiers are used across both documents so that test results in the VnV Report map directly to planned verification activities in the VnV Plan.	Section 4.3

2 Extras

Our extra is a research paper on the State of the Practice for Open-Source Neural Network Software. In this research paper, we identified a shortlist of 28 open-source Neural Network (NN) software packages and measured them across 9 qualities to have a pair-wise comparison using the Analytical Hierarchy Process (AHP).
The 28 libraries are:

- Apache MXNet
- Caffe
- Captum
- CatBoost
- Chainer
- CNTK
- cuDF
- DeepLearning4J
- Gensim
- Hugging Face Transformers
- JAX
- Keras
- LightGBM

- MLflow
- NeuroLab
- NLTK
- OpenCV
- Optuna
- PaddlePaddle
- PyTensor
- PyTorch
- PyTorch Geometric
- scikit-learn
- SHAP
- TensorBoard
- TensorFlow
- TorchVision
- XGBoost

We followed the steps outline in the Methodology for Assessing the State of the Practice for Domain X paper. Our addition to the methods outline in the paper was using our tool to accomplish the data collection and comparison portions.

3 Design Iteration (LO11 (PrototypeIterate))

The design of DomainX evolved through multiple iterations based on stakeholder feedback and usability observations. The goal of these iterations was to improve usability, ensure methodological correctness, and enhance data consistency.

3.1 AHP Framework Redesign

Previous Design

In the initial version, category importance was assigned using independent sliders. Each category was given a percentage weight directly by the user.

- There was no direct comparison between categories
- Users could assign inconsistent weights
- The approach did not correctly follow the actual AHP methodology

Figure 1: Initial weight assignment using independent sliders

Final Design

We replaced this with a pairwise comparison matrix based on the AHP method. Instead of assigning percentages directly, users compare categories relative to each other using the Saaty scale.

- Weights are computed automatically
- A consistency ratio (CR) is calculated to detect unreliable inputs

This change was important because the slider approach looked simple but often produced unreliable results. The matrix-based approach is slightly more structured, but it ensures the final weights are meaningful and consistent.

Figure 2: Pairwise comparison matrix with consistency validation

3.2 Visualization Improvements

Previous Design

The earlier version used 3D-style bar charts and only displayed a small subset of libraries.

- The 3D view made values harder to compare
- Not all libraries were visible at once

Figure 3: Previous 3D visualization with limited libraries

Final Design

We switched to a full ranking view using a standard 2D bar chart that shows all libraries.

- Easier to compare values across libraries
- No hidden data (All libraries are visible)

This change mainly came from usability issues. The previous chart looked visually appealing, but it was not practical when the number of libraries increased.

Figure 4: Improved visualization showing full ranking of libraries

3.3 Metric Definition Improvements

Previous Design

Originally, each metric had a single name field that was used both for display and internally in the system.

- Renaming a metric could break functionality (especially for automated metrics)
- There was no clear distinction between manual and automated metrics
- Input expectations were not well defined

Figure 5: Metric management interface

Final Design

We redesigned the metric configuration to separate concerns more clearly:

- Introduced an internal **metric key** separate from the display name
- Allowed users to rename metrics without affecting system logic
- Added an explicit distinction between **manual** and **automated** data sources
- Supported structured metric types (Boolean, Integer, Range, etc.)
- Added input categories and scoring rules for controlled data entry

Figure 6: Configuration for automated metrics

Figure 7: Configuration for manual metrics with predefined input categories

This change was mainly driven by a stakeholder requirement: they needed the ability to rename metrics freely without breaking automated data collection. Separating the internal key from the display name fixed this issue and made the system more robust.

3.4 Metric Value Input Improvements

Previous Design

Metric values were entered directly inside a table, with each row representing a library.

- Hard to navigate when many metrics were present
- Easy to lose track of which values were being edited

Figure 8: Row-based metric value input

Final Design
We introduced a popup-based interface for editing values.

- Users focus on one library at a time
- Inputs are grouped more clearly

This made data entry much more manageable, especially for domains with many metrics.

Figure 9: Popup-based metric value input interface

3.5 Data Input and Validation Improvements

Previous Design
All metric values were entered as free text.

- Flexible but inconsistent
- Same value could be entered in different formats (e.g., "yes", "Yes", "Y")

Final Design
We introduced structured inputs where possible:

- Boolean metrics now use dropdowns (Yes / No / Unclear)
- Metrics with predefined scoring (e.g., ranges or rating scales) also use dropdown selections

Free-text input is still allowed for metrics that require flexibility.
Instead of removing flexibility entirely, we limited it only where it caused problems. This helped standardize inputs without making the system too rigid.

3.6 User Feedback and Iteration

User feedback was collected through task-based testing with an external user (Ryan).

Overall Observation

Basic tasks such as domain creation, and exporting data were straightforward. However, usability issues appeared in more complex workflows involving metrics.

Key Findings and Changes

Metric Creation

Ryan noted:

> "If the scoring rule is not clicked, the system does not allow saving, but there is no clear prompt or warning message."

This showed that although required fields (e.g., metric name, scoring rule, input category) were already enforced by the system, there was no feedback indicating which fields were missing. As a result, the system appeared unresponsive when users attempted to create a metric.

Change: We added explicit validation feedback to indicate missing required fields, making it clear why a metric could not be created.

Metric Value Input

Ryan reported:

> "It was difficult to find where to fill in the manual metrics... I had to scroll or search to locate them."

This showed that the table-based input interface did not scale well.

Change: We introduced a popup-based interface to allow users to focus on one library at a time.

Input Consistency

Free-text inputs led to inconsistent data entry.

Change: We added dropdown inputs for metrics with predefined values (e.g., Boolean, ranges, scoring scales), while keeping free-text where needed.

Summary

The feedback helped identify usability gaps in metric-related workflows. The resulting changes focused on improving clarity, reducing user effort, and ensuring more consistent data entry.

4 Design Decisions (LO12)

[Reflect and justify your design decisions. How did limitations, assumptions, and constraints influence your decisions? Discuss each of these separately. —TPLT]

5 Economic Considerations (LO23)

Our project is meant to be an open-source tool to be used for the research community, both active researchers and students.

Currently, we already have one user, the master's student who is researching for the Robotics software domain. The number of potential users is at minimum the amount of people who would be researching a domain.

Since our project is open source, marketing efforts would focus on raising awareness rather than selling a product. Strategies could include:

1. Promoting through word-of-mouth by Dr. Spencer Smith, development team and past users of the tool.
2. Presenting our research paper that mentions the use of this tool at academic conferences.
3. Posting online about our tool for anyone who is interested in seeing the results of this type of research.

6 Reflection on Project Management (LO24)

6.1 How Does Your Project Management Compare to Your Development Plan

Our team mostly followed the Development Plan we laid out. But as the project progressed, we made adjustments to better align with the reality of the project, and update the Development Plan accordingly.

Team Meeting Plan: The team meeting plan originally stated that we would meet as a team every Monday virtually. But starting with the second semester, we started to meet when needed. This is due to the nature of our team, where we had two subteams so oftentimes, not everyone had to attend every meeting.

Team Communication Plan: Originally, we planned on only using Microsoft Team's to communicate. But for our project, we wanted a communication platform that allowed for multiple different chat rooms, which Team's couldn't do. Therefore, we updated our communication plan and used Discord as our team's main communication platform.

Team Member Roles: The roles mostly stayed the same, the only change was the Team Leader moving from Ghena to Fei.

Workflow Plan: At the start, the workflow plan wasn't followed as tightly. Members weren't properly creating issues for their work, or labeling the issues themselves. However, towards the second half of the project, the workflow plan was followed exactly.

We followed the expected technology to build the web application, namely React for frontend, Django for backend, and MySQL for database. And implemented the linters PEP 8, Black, isort, and Flake8.

Since McMaster actually deploys its application on-premise, we did not need to use a cloud platform like Amazon Web Services (AWS).

6.2 What Went Well?

With the implementation of GitHub workflows and Run & Debug on VSCode, it was extremely easy to develop the application locally. Later on as we added testing frameworks and mandated the requirement that new features must have unit tests, and pull requests cannot be merged unless all unit test passes, it removed a lot of uncertainty that new changes would break existing systems. Furthermore, with pre-commit linting tools automating most syntax issues, the overall development was easy.

On the infrastructure side, since we used docker containers, deploying new changes was very easy, since all we need was pull the updated GitHub code and recreate the containers.

Being strict on documentation, particularly for development and infrastructure purposes reduced a lot of questions and helped get new members of the development team up and running quickly.

6.3 What Went Wrong?

Since everyone on the team was busy, there were times when team members had to wait for extended periods for their pull requests to be reviewed. Additionally, team members had different experiences and expectations regarding how issues should be structured. Some members weren't creating issues for the tasks they were working on, while others were creating too many unnecessary issues. This was detrimental because the number of issues opened and closed was a key metric used to track team contributions.

6.4 What Would You Do Differently Next Time?

Next time, we would use the GitHub Project board more frequently. While it requires some effort to set up and maintain, it greatly improves transparency by making it easier to see what other team members are working on. Since we aren't holding daily stand-up meetings, the board would help keep everyone on track and allow us to identify potential issues earlier.

7 Ethics and Equity (LO18)

We incorporated equity throughout the development process by establishing a team expectation plan that included clear communication and problem resolution guidelines. This created an environment where all team members could contribute ideas, provide feedback, and voice concerns safely and respectfully, ensuring that diverse perspectives were considered in decision-making.

In the design of the product, we applied principles of universal design by maintaining a consistent layout across all pages of the web application, making

it easier for users to navigate and understand the interface. We also provided clear and timely user feedback to ensure that users are informed about system actions and outcomes. These design choices help make the application more accessible and intuitive for users with varying levels of experience and ability.

Overall, our approach supports both equitable collaboration within the team and an inclusive user experience for all stakeholders.

8 Reflection on Capstone

Overall, our capstone project allowed us to further strengthen both our web development and project management skills. As we were responsible for the entire lifecycle of the application. From the problem statement to designing and implementing the solution, we each took on multiple roles throughout the process.

This experience closely mirrored real-world industry expectations, where teams must work within deadlines and constraints. We had to make thoughtful decisions about prioritization, recognizing that limited time and resources meant not every feature could be implemented. As a result, we focused on delivering the most impactful functionality while maintaining quality.

Through this process, we gained valuable experience in balancing technical development with planning, communication, and adaptability, all of which are essential skills in a professional software engineering environment.

8.1 Which Courses Were Relevant

SFWRENG 4HC3: Human Computer Interfaces
SFWRENG 3DB3: Databases

The above two courses were particularly relevant to our capstone, due to our project being a web application with users. SFWRENG 3DB3 was particularly helpful during the design process, when we had to design our database to accommodate our business logic.

8.2 Knowledge/Skills Outside of Courses

Web development and project management experience from past co-ops tremendously helped with the project. Since many members of the group was already familiar with certain tools, libraries and frameworks, we were able to play into our strengths and build our technology stack on what was already familiar.
